CONTRIBUTION TO THE COMPILATION OF ALLUVIAL CHANNEL DATA

Study supported by PIDDAC

March 1986

ABSTRACT

LNEC's contribution to the compilation of alluvial channel data is a series of data sets which were corrected and added to the "Extension of World Flume Data with bedform dimension and celerity data" prepared by DELFT HYDRAULICS LABORATORY 1982, inspired by "A Compendium of Solids Transport Data for Mobile Boundary Channels" of PETERSON and HOWELLS 1973.

The "Compilation of Alluvial Channel Data", undertaken by BROWNLIE 1981, was used to evaluate the reliability of most of the existing data and to correct entries which, by a systematic or an individual error, were mistaken. New records, selected by the scanning of reports and articles, including river and flume data were added, special attention being paid to the collection of data from Portuguese rivers. Also added were some of the records not included in the Delft Hydraulics Laboratory Compilation and presented by Brownlie. A general characterization of the final data sets was also made having in mind the judgement of their usefulness in particular studies.

RESUMO

A contribuição do LNEC para a compilação de dados de escoamentos fluviais consiste num conjunto de dados adicionados e corrigidos à "Extension of World Flume Data with bedform dimension and celerity data" preparada por DELFT HYDRAULICS LABORATORY 1982, inspirada em "A Compendium of Solids Transport Data for Mobile Boundary Channels" de PETERSON e HOWELLS 1973.

Recorreu-se à "Compilation of Alluvial Channel Data", elaborada por BROWNLIE 1981, para avaliar a qualidade da maioria dos dados existentes e para alterar valores incorrectos, devido a erros sistemáticos ou esporádicos. Adicionaram-se novos registos relativos a rios e canais laboratoriais, seleccionados por consulta bibliográfica, sendo dedicada especial atenção à inclusão de dados de rios portugueses. Também se incluiram alguns registos que, não constando da compilação elaborada pelo Laboratório de Delft, foram apresentados por Brownlie. Procedeu-se à caracterização geral da versão final dos dados com o objectivo de possibilitar a avaliação da sua utilidade para diferentes tipos de estudos.

authors of the added data sets

1 - INTRODUCTION

The Laboratório Nacional de Engenharia Civil (LNEC) started recently a research programme on resistance to flow in alluvial channels. The final results of this study will significantly depend on the existence of large amounts of reliable river and flume data. So, it was decided to extend and correct the existing data compilations, not as criticism but simply to contribute to a better understanding of flow phenomena in channels with sediment transport.

PETERSON and HOWELLS 1973 took the first step towards the development of a computerized data compilation which contained 6606 records, each consisting of observations of 10 basic hydraulic variables. BROWNLIE 1981 made a very serious effort to avoid deficiencies in the data compilation of Peterson and Howells and included approximately 2500 new records. His compilation of alluvial channel data is relatively free from errors as a careful item-by-item check was made. DELFT HYDRAULICS LABORATORY 1982 extended the compendium of PETERSON and HOWELLS 1973 mainly by the addition of data related to bedform dimensions and celerities, and granulometric data.

The objectives of the work undertaken at LNEC are:

- 1- to introduce corrections in the extended data compilation of the Delft Hydraulics Laboratory (DHL) according to the original sources (phase 1);
- 2- to extend the data compilation obtained in phase 1 with new data, from existing literature, specially data from Portuguese rivers (phase 2);
- 3- to perform as many tests as possible on all data sets to correct internal coherence errors (phase 3).

At the same time, some of the 2500 records added by BROWNLIE

1981 (data sets known as COSTELLO; FOLEY; KENNEDY; ONISHI; SONY; TAYLOR; SIMONS; KNOTT) was included with the "format" adopted by the Delft Hydraulics Laboratory.

In this document, a report is presented on the work developed in phases 1 and 2; the final report on phase 3 would be premature at this moment. No other reference is made to the data added by BROWNLIE 1981 because no significant contributions were introduced to these data at LNEC.

The results of this effort are not intended to be the answer to the aspiration of having a reasonable amount of accurate data, but rather as a contribution towards this objective.

The data collection is available in magnetic tape format from the Laboratório Nacional de Engenharia Civil.

2 - RECORDED VARIABLES

Both PETERSON and HOWELLS 1973, and BROWNLIE 1981 recorded the values of 10 variables for each observation in a river or flume cross-section. In the first reference, these variables were given in terms of British units; in the second, all measurements were converted into consistent SI units. The referred variables were:

1. Discharge, Q;
2. Width (top width of the channels), B;
3. Mean flow depth, h;
4. Energy slope, S;
5. Median particle size of bed material, D₅₀;
6. Geometric standard deviation of bed-particle size, G;
7. Specific gravity of bed material, d;
8. Concentration of bed material load, C;
9. Temperature, T;
10. Bedform (BF), given by the code:
 - 0 - not observed;
 - 1 - plane bed (no motion);
 - 2 - ripples;
 - 3 - dunes;
 - 4 - transition;

- 5 - plane bed (sheet flow);
- 6 - standing waves;
- 7 - antidunes;
- 8 - chutes and pools.

The adaptations introduced by the Delft Hydraulics Laboratory to the data set of Peterson and Howells were the following:

- original data in British units were converted into SI units;
- in addition to D₅₀ and the geometric standard deviation of bed-particle size (gradation coefficient) some other characteristic particle diameters were included: D₁₆, D₃₅, D₆₅, D₈₄, D₉₀, DM (where D_n is the particle size for which n% in weight of the sediment mixture is finer, and DM is the mean diameter);
- fall velocity, mean length of bedforms, mean height of bedforms, mean celerity of bedforms and flume length were added when available;
- a few new data sets were included.

After the contribution of the Delft Hydraulics Laboratory, the items of each record (inserted in a typical F13.6 FORTRAN format) became:

Item	Remarks
ID	- Identification number, tabulated in each record;
Discharge	- Channel discharge (m ³ /s);
Width	- Channel width at the tabulated discharge (m);
Depth	- Channel flow depth (m);
Slope	- Channel water surface slope (m/m);
D ₅₀	- D ₅₀ of bed material (mm);
Gradation	- Gradation coefficient of bed material;
Specific gravity	- Specific gravity of bed material;
Charge	- Total concentration of transported bed material by weight of water-sediment discharge (ppm);
Temperature	- Temperature of water (°C);
BF	- Bedform, given by the same code as the one adopted by BROWNLIE 1981;
D ₁₆	- D ₁₆ of bed material (mm);
D ₃₅	- D ₃₅ of bed material (mm);
DM	- DM of bed material (mm);
D ₆₅	- D ₆₅ of bed material (mm);
D ₈₄	- D ₈₄ of bed material (mm);
D ₉₀	- D ₉₀ of bed material (mm);
Fall velocity	- Fall velocity (m/s);
Bedform length	- Bedform length (m);
Bedform height	- Bedform height (m);

Vel. of bedform - Velocity of bedform (m/hr);
Length of flume - Length of flume (m);
Code - Code = 0 : original report not yet scanned
for extension of data set;
Code = 1 : original report scanned for
extension of data set;
Group Number - F13.6 - Number to identify the source;

Data not given in source references is indicated in the tabulation by a negative quantity (usually -1.0) or a zero.

Appendix 1 lists the data sets of the DHL's compilation. All the work performed at LNEC was developed maintaining the indicated record format of DHL.

3 - CONTRIBUTION TO THE COMPILATION OF ALLUVIAL CHANNEL DATA

As already mentioned, two kinds of adaptations of the DHL's compilation were tried at LNEC : its correction and its extension with new data sets.

The correction was initially made checking again the data published in the existing literature and, in a second step, by the comparison of the obtained results with Brownlie's compilation which was confirmed to be relatively free from errors.

Table 1, where Brownlie's compilation and DHL's compilation are also characterized, gives a general picture of the work developed at LNEC. Four types of general attitudes were adopted:

- DHL's records were practically or completely maintained;
- Brownlie's records were practically or completely maintained;
- serious corrections were introduced;
- new data were added.

Appendix 2, whose first page is a table indicating the position of variables in each record, contains the data sets which were significantly changed; Appendix 3 contains the added

data sets.

Next, a detailed description of the work done is presented.

3.1 - Unchanged and deleted data sets

Some data sets remained completely unchanged: C.S.U.; GILBERT; USWES (TURBIDITY TESTS); BOGARDI & YEN; WILLIS, COLEMAN & ELLIS; U.B.C.; W. BENGAL; ZNAMENSKAYA; SOUTHAMPTON, B; LEOPOLD; LIGHT WEIGHT; CHITALE; ANSLEY; and DELFT HYDRAULICS LABORATORY.

OXFORD data set was deleted because it corresponds to WILLIS, COLEMAN & ELLIS set, which seems to be more complete.

3.2 - Improved data

BROWNLIE 1981 mentions the following corrections that he introduced to the Peterson and Howells' compilation:

- grain size in the data of TOKYO, SATO & KIKKAWA;
- 3 concentration values in the data of STRAUB;
- discharge (which was erroneously substituted by the flow velocity) in the data sets of ABDEL-AAL, and VANONI & HWANG;
- slope and depth (which were interchanged) in the previous two data sets;
- sediment concentration in the data of WILLIAMS due to the consideration of the dry unit weight per time instead of submerged weight;
- sediment concentration in the data for the INDIA CANALS (CHAUDRY, SMITH and VIGIL 1970) as a consequence of units misunderstanding.

All these errors were eliminated from the data compilation of the Delft Hydraulics Laboratory.

Other errors, detected in discharge, width, depth, charge, temperature and DM were corrected whenever differences from that

data compilation were greater than approximately 10%.

In the compilation by DHL all the characteristic diameters, including D₅₀, were obtained by geometric interpolation in the cumulative granulometric curve, and the gradation coefficient was calculated, instead of considering the D₅₀ and the gradation coefficient given in each source report. This procedure seems to be questionable; so, in the present work it was decided to keep the original values of D₅₀, gradation coefficient and specific gravity whenever available.

A large number of improvements was performed in the data sets known as NOMICOS, VANONI & BROOKS, BROOKS, and VANONI & HWANG. These improvements were the following (Appendix 2):

- a) NOMICOS: all runs with stabilized bed (VANONI and NOMICOS 1960) were eliminated; data from table 7 of BROOKS 1958 were added to this data set.
- b) VANONI & BROOKS: bed condition contained in BROOKS 1958 and bedform dimensions contained in VANONI and HWANG 1967 made possible the inclusion of bedform code in this data set.
- c) BROOKS: these data were modified according to BROOKS 1958; bedform codes were added and runs with "meander" bedform condition were eliminated.
- d) VANONI & HWANG: very significant corrections were made in discharge, width, depth, slope, bedform characteristics and channel length.

3.3 - New data sets

Eight new data sets (ANNAMBHOTLA, SAYRE & LIVESEY; HILL, SRINIVASAN & UNNY; KENNEDY & BROOKS; NORDIN A; NORDIN B; WILLIAMS B; TEJO A; TEJO B) with a total of 415 records were added to the compilation by DHL. PORTUGAL data set (containing 219 records) was renamed MONDEGO, to distinguish from two Portuguese data sets which were added; it is described in Appendix 4 and printed in Appendix 3 as new data because special attention is paid to

Portuguese rivers.

A summary description of measuring equipment and procedures adopted by the authors of the sources scanned for new data is given in Appendix 4, under the proposed designations. The objective of this description is a quick elucidation of potential users. Anyway, reading of the original reports and articles may be still necessary.

4 - CHARACTERIZATION OF THE EXISTING DATA

Each study has its own needs in what concerns the variables involved. For example, a data set which does not include the types of bedforms installed in the bed cannot be used to evaluate the reliability of a given bedform prediction criterion. Nevertheless, it can probably be used to make a corresponding study on resistance to flow. A data set which does not include the bedform dimensions is of no use to the establishment of useful relations between their dimensionless versions and other dimensionless flow properties.

So, it seems to be important to know which are the variables actually recorded in each data set. All data sets include the values of discharge, width, and depth. Table 2 registers the number of significant values (non-negative and/or non-zero) of the remaining important variables of each data set. It also distinguishes river and flume data.

It should be emphasized that only about 20 % of the compiled data was measured in rivers or on comparatively large canals; most of the corresponding data give no information on bedform types and dimensions. Laboratory data is also somewhat scarce on

TABLE 2

APPENDIX 4

SUMMARY OF PROCEDURES AND EQUIPMENT USED BY THE AUTHORS
OF THE ADDED DATA SETS

SUMMARY OF PROCEDURES AND EQUIPMENT USED BY THE AUTHORS
OF THE ADDED DATA SETS

1. ANNAMBHOTLA, SAYRE & LIVESEY

The main objective of the investigation carried out by ANNAMBHOTLA et al. 1972 was to explore various statistical methods for describing bedforms in large rivers with a view towards relating them to the resistance to flow. A reach of Missouri River near Omaha was selected as a study reach for obtaining field data of longitudinal bed profiles.

During the period of this investigation, the river width was approximately 183 m and the average longitudinal water surface slope about 1 m per 6.86 Km. Mean flow depths ranged from about 3.05 m to 4.27 m and mean flow velocities from about 1.07 m/s to 1.59 m/s. The median size of bed material was 0.2 mm. With a few exceptions the discharge of the river ranged from 840 m³/s to 980 m³/s. Water temperature ranged from about 4°C to about 27°C.

Bed profiles were obtained along three longitudinal lines that were located at the center and at approximately the quarter points of the cross-sections, about 46 m from either bank. The sensing unit for obtaining the longitudinal river bed profiles was a Model ES-1025 Bludworth Ultrasonic Depth Recorder mounted in a sounding boat. A detailed description of measurements and processing of bed profiles is offered by ANNAMBHOTLA et al. 1972. No reference is made on how discharge, cross section area (i. e. mean flow velocity, which was tabulated by the authors referred to) and slope were measured. So, in this new data set, mean flow depth was calculated assuming a 183 m top width, and the tabulated values of discharge and mean velocity which were presented by ANNAMBHOTLA et al. 1972. No concentration values are

available in this source.

2. HILL, SRINIVASAN & UNNY

In the study carried out by HILL et al. 1969, a method is proposed for predicting the replacement of a bed which is initially flat under high discharge and high sediment transport conditions by either dunes or ripples.

The experiments were conducted in a 37 m long recirculating flume, 0.61 m wide and 0.61 m deep. The flume was of concrete and the flume bed was laid level without any slope. This allowed the sediment bed to find its own equilibrium slope with each discharge. Three different grades of sand: very fine, fine, and medium, were used. The viscosity of the water was varied over a wide range by controlling the temperature between 21°C and 66°C.

The discharge was measured with a calibrated orifice meter located in the vertical portion of a delivery pipe directly connected to the flume. The water temperature was controlled by the provision of four immersion heaters. The water surface slope was measured as a drop in static head between two sections 9.8 m apart by means of Equibar pressure meter. The water surface and bed levels were recorded to obtain the average depth of flow.

The first three records of this data set are the mean values of the groups defined by narrow depth ranges, corresponding to the preliminary experiments carried out by HILL et al. 1969. The remaining 31 records correspond to the summary of experimental data for runs at different temperatures measured by the authors referred to. Bedforms were all classified as transition (BF=4).

3. KENNEDY & BROOKS

The main point to be solved by the study of KENNEDY and BROOKS 1965 was whether two or more different depths of flow are possible for a given discharge and slope.

Complete details and thorough discussions of apparatus, the techniques used in measuring the various quantities, and the procedures used in reducing the data were given by BROOKS 1958. The experiments were performed in a 0.85 m wide, 18.3 m long recirculating tilting flume. The mean depth of flow in the open channel was controlled by the amount of water in the system. The flume slope could be set at any desired value and easily adjusted during the course of a run. A point gage mounted on a carriage that moved along rails on the flume was used to measure the elevations of the water surface and sand bed relative to the flume. Water surface elevations were measured during the run at 1.22 m intervals along the flume, and bed elevations were measured after the pump had been stopped and the bed levelled in 1.22 m reaches with a special leveller. The discharge was measured with the Venturi meter located in the return pipe. To determine the total sediment transport rate, 12 or more samples of 1 liter each were siphoned through special samplers from the vertical section of the pipe above the pump in the flow circuit. The individual 1-liter samples were then passed through filter paper, and the sediment retained was dried and weighed. A sieve analysis was performed on the composite of all samples for each run. These analyses showed that the geometric mean sieve diameter, DM, was 0.142 mm, and the gradation coefficient was 1.38.

4. NORDIN, A

The study performed by NORDIN 1964 was based principally upon data from a reach of the Rio Grande near Bernalillo, New Mexico.

Measurements were carried out in two sections of the river, where permanent cables were installed. The observations were approximately concurrent, except for a few dates, when water discharge was measured only at the upstream section. For these dates, the cross-sectional area of the downstream section was determined by sounding, and the area so determined was used with discharge from the upstream section to obtain mean velocity.

Water-surface elevations were obtained from staff gages referred to a datum of mean sea level. Slopes of the energy gradients were determined as the drop in elevation of the energy gradients divided by the distance, 2511 m, between observation sections, and were assumed applicable to both of them. Suspended-sediment samples were collected with a US D-49 sampler, which collects samples from the water surface to about 0.1 m above stream bed. Usually, 3 to 15 samples of bed material were collected from the upper 2 to 5 cm of the bed; no reference is made to the sampler. The samples were analysed separately by sieves to define the median diameter and the gradation coefficient of bed material.

Bed-load transport was not measured. Sediment transport rates were computed by the modified Einstein method and by the method proposed by LAURSEN 1958; for several observations, transport rates were estimated using the Einstein bed-load function. As a consequence of these procedures, concentration of transported sediment was not included in LNEC's compilation.

5. NORDIN, B

In broad terms, the study by NORDIN 1971 was designed to investigate the statistical properties of stream bed profiles. Profiles from four different channels were selected for these analyses. Three of the channels were recirculating laboratory flumes. The other channel was Atrisco Lateral near Bernalillo, New Mexico.

The dimensions of the flumes were: 0.20 m wide by 9.15 m long, 0.61 m wide by 18.3 m long, and 2.44 m wide by 61 m long. Atrisco Lateral was approximately 16.75 m wide, and the profiles were obtained about midway in a straight reach 3657.6 m long. The median diameters of bed material ranged from 0.23 mm to 0.35 mm.

Values of flow parameters (mean depth, mean velocity, slope, water temperature) were tabulated in NORDIN 1971, no reference being made on the measuring equipment; six different discharges were selected for analysis.

Profiles of the bed elevations were obtained with a sonic depth sounder except for the smallest flume, where the profiles were traced on a stripchart from the plastic side-walls of the flume. Only longitudinal profiles were available for Atrisco Lateral and the smallest flume; for the other flumes, time records of bottom level at a section were available with the longitudinal profiles. The bedform dimensions were obtained by averaging the corresponding values of each group of bed profiles associated with different flow conditions.

This data set consists of eleven records with different values of discharge, depth, slope, and temperature, and the mean values of statistical data for heights and lengths of bedforms.

6. WILLIAMS, B

WILLIAMS 1967 presented a study where a laboratory flume was used to analyse sediment transport phenomena in a series of runs with a coarse (1.35 mm) sand bed for three flow depths.

The test section of the flume was 15.85 m long and 0.305 m wide. Its slope was adjustable from horizontal to about 0.02 using chain hoists.

The discharge was read by a bend meter. This was a common pipe elbow with holes drilled through the wall at the inner and outer vertices of the pipe curvature. These holes were connected by tubing to a manometer, and the difference in pressure between the inside and the outside parts of the bend was a direct indication of discharge flowing through the elbow. The slope of the flume was determined by setting up a surveyor's level independent of the flume structure and measuring the vertical drop in a known distance downstream. The slope of the bed (and water surface) relative to the flume rails was taken from the plotted profiles. Slope relative to flume rails and slope of flume rails themselves were combined to give the actual bed (and water surface) slope. Flow depths were obtained from these profiles. Sediment transport rate was measured by means of a collection box located downstream of the flume. To ensure representative samples, the collection period was always long enough to allow at least several bedforms to move out of the flume and into the collection box. Bedform characteristics (type of bedform, wavelengths, waveheights and celerities) were measured. Two or three small pieces of wood were individually timed for rate of movement as they floated along the water surface. This surface velocity was multiplied by 0.80 to provide a rough estimate of the mean flow velocity. The actual value of mean velocity was obtained by

dividing the discharge by cross-sectional area, based on depth as given in profiles. Material in the collection box and material left on the bed were sampled after the completion of each run. The samples were dried and sieved, providing the sediment-size characteristics.

7. MONDEGO

These data correspond to PORTUGAL file from DHL's compendium with discharge entries corrected and characteristic diameters added. So, in fact it does not correspond to the addition of new data.

The data presented in CUNHA 1969 for the period from October 1965 through June 1966 were collected as part of Baixo Mondego Programme dedicated to quantify the sediment transport and to analyse the relationships between this quantity and the parameters which characterize flow and bed material.

Two measuring stations were used, the main one in Coimbra at the upstream end of the stretch to be studied, i.e. about 40 Km from the river mouth, and the other at Vila Pouca, about 10 Km downstream.

Whereas data on the bed-load in the whole cross section of the river are obtained at Coimbra station, the other station at Vila Pouca covers one of the river branches alone.

At Coimbra the river has a width of about 185 m, which changes comparatively little with the water level, and the river bed has a slope of about 0.0008. The maximum river flow recorded during the observations was about 1200 m³/s, which corresponds to a frequency of little less than once every two years.

At Vila Pouca station the river is about 70 m wide, the banks are almost vertical and the bed slope is about 0.00075. The

maximum recorded flow of about $200 \text{ m}^3/\text{s}$ is practically the one that cannot be exceeded in this river branch without flooding the marginal fields.

The bed material granulometry was established by collecting a series of 65 samples along the river bed and its affluents. The two granulometric curves were obtained by taking the characteristic diameters of the samples collected in the neighbourhood of Coimbra and Vila Pouca sections. At Coimbra, D_{50} is 2.6 mm, and at Vila Pouca, D_{50} is 2.2 mm. For both sections the specific gravity is 2.64.

Limnographs were mounted in both stations and the flow was frequently measured with current meters. The longitudinal slope of the free surface was measured by means of two scales about 500 m apart that were read simultaneously. Once or twice a week, the cross-sectional profiles were traced by sounding.

The bed load was measured with an "Arnhem" (BTMA) instrument, developed at the Delft Hydraulic Laboratory, the calibration curve presented by VAN TIL 1956 having been used. Velocities were measured in points distributed in the river cross section, in five verticals at Coimbra and three at Vila Pouca. Ten measurements were successively carried out at each point and a mean was calculated in order to compensate the fluctuations of bed load, due to the bedforms in the river bed.

The suspended load was also measured at some points with US D-49 and US P-50 suspended-sediment samples developed in the United States by the Federal Inter-Agency Committee on Water Resources. According to these measurements the suspended load in Mondego River is comparatively small with respect to the bed load.

8. TEJO, A

Two cross sections were selected by FONSECA 1971 to measure hydraulic characteristics of flow, including sediment transport, in river Tagus near Santarém. One of them was Santarém itself, situated 350 m downstream of Ponte D. Luís, and the other, Porto de Courela, situated 2750 m upstream of Ponte D. Luís.

The observation periods for each cross section were not absolutely concurrent; in fact, at Santarém it went from March 1970 to January 1971, while at Porto de Courela it went from July 1970 to January 1971.

The first 10 records of this data set were measured at Porto de Courela and the remaining 25 at Santarém.

85 samples of bed material collected by tubular samplers along a 180 km long reach, allowed a complete characterization of the river bed material. Specific gravity was about 2.65. At Santarém the D₅₀ is 0.9 mm, and at Porto de Courela it is 0.75 mm.

In each cross-section, the following routine observations were performed: water temperature, cross-section topography, point velocities, water surface slope, bed-load transport, and suspended sediment load. The adopted procedures were approximately the same as described previously about MONDEGO data.

9. TEJO, B

From 1971 to 1977, the hydraulic parameters of three cross-sections were measured (HENRIQUES 1982). These cross-sections were Omrias (near Santarém), Almourol (45 km upstream of Santarém), and Tramagal (15 km upstream of Almourol).

At Omrias the observation period went from February 1971 to

March 1977. 794 values of discharge, 685 values of bedload discharge, and 268 values of suspended load were measured. Only 200 observations were concurrent and were included in this data set. The value of D₅₀ corresponding to the bed material was 0.73 mm.

Almourol section was studied from October 1972 to May 1977. The number of observations of discharge, bedload discharge, and suspended load were respectively 226, 150, and 58, 19 being concurrent. The median diameter of bed material was 1.16 mm.

Finally, in Tramagal section, the observations lasted from October 1972 to April 1977. 169 records of discharge were obtained along with 117 of bedload discharge and 35 of suspended load. Only 14 records were included for concurrency reasons. D₅₀ of bed material was 1.2 mm.

The specific gravity of the bed material was about 2.65 for the three cross-sections. The river widths were basically the same and hardly changed with discharge, except at Omrias for values of discharge greater than about 4000 m³/s.

The measuring equipment was the same as the equipment used in Mondego at Coimbra and Vila Pouca.
